Agenda

- 1. OLTP vs OLAP
- 2. Data Cubes
- 3. HTAP

Reading Materials

Fundamental of Database Systems (7th Edition)

Chapter 29 - Overview of Data Warehousing and OLAP

1. OLTP vs OLAP

So far we've been dealing with OLTP

OLTP: OnLine Transactional Processing

- Often used to store and manage relevant data to the day-to-day operations of a system or company
 - e.g., ATM transactions, online hotel bookings
- INSERT, UPDATE, DELETE commands
- Handles real-time transactions (response times often in milliseconds)
- ACID properties are often important

This is where relational databases shine!

Ok, so what's OLAP?

OLAP: OnLine Analytical Processing

- Also known as decision support or business intelligence (BI), but now BI has grown to include more (e.g., AI)
- A specialization of relational databases that prioritizes the reading and summarizing large volumes (TB, PB) of relational data to understand high-level trends and patterns
 - E.g., the total sales figures of each type of Honda car over time for each county
- "Read-only" queries

Contrast this to OLTP

- "Read-write" queries
- Usually touch a small amount of data
 - e.g., append a new car sale into the sales table

How is OLAP Performed?

Usually, OLAP is performed on a separate data warehouse away from the critical path of OLTP transactions (a live/transactional database).

This data warehouse is periodically updated with data from various sources (e.g., once an hour or once a day)

- This is through a process of ETL (Extract, Transform, Load)
 - Extract useful business that needs to be summarized, transform it (e.g., canonicalize values, clean it up), load it in the data warehouse
- By doing it periodically, this data warehouse can become stale

How is OLAP Performed?

Usually, OLAP is performed on a separate data warehouse away from the critical path of OLTP transactions (a live/transactional database).

Why?

- Because OLAP queries end up reading most of the data, and will prevent OLTP queries from taking precedence
 - it is more important to ensure that sales are not prevented than to make sure that a report for a manager is generated promptly
 - the latter will anyway take a long time, so might as well have them wait a bit longer
- It's OK if the warehouse data is a bit stale.

OLAP in Data Warehouses

Here are some data warehouses that you might have heard of

Data Warehouse vs Data Lake

Data warehouse:

structured data (schema-on-write) expensive for large data volumes managers and business analysts

Image source: https://www.sap.com/insights/what-is-a-data-lake.html

11

Data Lake vs Data Warehouse

Data lake:

raw data, can be unstructured (schema-on-read) low-cost storage, but no transactions, data quality checks data scientists and engineers

Image source: https://www.sap.com/insights/what-is-a-data-lake.html

We will focus on the following two aspects of OLAP systems

#1 Data Model

• Relational vs multi-dimensional schema

#2 Storage Format

• Row vs column store

#1 Data Model: Multi-dimensional Model

The multi-dimensional data model includes two types of tables:

- Fact table
 - Contain the actual metrics or measurements of business processes. Store quantitative data (numbers that can be aggregated).
 - E.g., Sales amount, Quantity sold
 - Typically has many rows but fewer columns
 - Usually contains foreign keys that link to dimension tables
- Dimension table
 - Contain descriptive attributes that provide context to facts
 - Store qualitative data
 - E.g., Product dimension (name, category, brand), Time dimension (date, month, year)

Multi-dimensional Schemas

Star schema:

• Consists of a fact table with a single table for each dimension.

Multi-dimensional Schemas

Snowflake Schema:

• It is a variation of star schema, in which the dimensional tables from a star schema are normalized to eliminate redundancy

Figure 29.8 A snowflake schema.

Comparison with the Relational Model

The relational model (used by OLTP) keeps tables normalized

 Minimal updates required for data inserts and deletes => help improve transaction performance

In the multi-dimensional model, the fact table is often in 3NF, but the dimensional tables are denormalized.

- This means columns in a table contains data which is repeated throughout the table => help improve read performance.
- Data is stored in fewer tables, which removes the overhead of having to perform complex joins => helps improve read performance.

#2 Storage Format: Row vs Column Store

row-store

column-store

- Store all attributes of a tuple together
- Storage like "row-major order" in a matrix •
- Store all rows for an attribute together
 - Storage like "column-major order" in a matrix

Q: Which format do you think is better suited for OLTP vs OLAP?

Acknowledgement: Slides adapted from VLDB 2009 Tutorial on Column Stores

#2 Storage Format: Row vs Column Store

row-store

+ easy to add/modify a record- need to read unnecessary data

+ only need to read in relevant data

- tuple write require multiple accesses

Telco Data Warehousing example

"One Size Fits All? - Part 2: Benchmarking Results" Stonebraker et al. CIDR 2007

QUERY 2 SELECT account.account_number, sum (usage.toll_airtime), sum (usage.toll_price) FROM usage, toll, source, account WHERE usage.toll_id = toll.toll_id AND usage.source_id = source.source_id AND usage.account_id = account.account_id AND toll.type_ind in ('AE'. 'AA') AND usage.toll_price > 0 AND source.type != 'CIBER' AND toll.rating_method = 'IS' AND usage.invoice_date = 20051013 GROUP BY account.account_number

Telco example explained: read efficiency

row store

read pages containing entire rows

one row = 212 columns!

is this typical? (it depends)

read only columns needed

in this example: 7 columns

caveats:

- "select * " not any faster
- clever disk prefetching
- clever tuple reconstruction

Acknowledgement: Slides adapted from VLDB 2009 Tutorial on Column Stores

Telco example explained: compression efficiency

Columns compress better than rows

- Typical row-store compression ratio 1:3
- Column-store 1 : 10

Why?

- Rows contain values from different domains
 - More entropy, difficult to dense-pack
- Columns are much more homogeneous
- Caveat: CPU cost (use lightweight compression)

We'll read more about column stores

Abstract

This paper presents the design of a read-optimized relational DBMS that contrasts sharply with most current systems, which are write-optimized. Among the many differences in its design are: storage of data by column rather than by row, careful coding and packing of objects into storage including main memory during query processing, storing an overlapping collection of column-oriented projections, rather than the current fare of tables and indexes, a non-traditional implementation of transactions which includes high availability and snapshot isolation for read-only transactions, and the extensive use of bitmap indexes to complement B-tree structures.

We present preliminary performance data on a subset of TPC-H and show that the system we are building, C-Store, is substantially faster than popular commercial products. Hence, the architecture looks very encouraging.

1. Introduction

Most major DBMS vendors implement record-oriented storage systems, where the attributes of a record (or tuple) are placed contiguously in storage. With this *row store* architecture, a single disk write suffices to push all of the fields of a single record out to disk. Hence, high performance writes are achieved, and we call a DBMS with a row store architecture a *write-optimized* system. These are especially effective on OLTP-style applications.

In contrast, systems oriented toward ad-hoc querying of large amounts of data should be *read-optimized*. Data warehouses represent one class of read-optimized system,

To copy otherwise, or to republish, requires a fee and/or special permission from the Endowment

Proceedings of the 31st VLDB Conference, Trondheim, Norway, 2005 in which periodically a bulk load of new data is performed, followed by a relatively long period of ad-hoc queries. Other read-mostly applications include customer relationship management (CRM) systems, electronic library card catalogs, and other ad-hoc inquiry systems. In such environments, a *column store* architecture, in which the values for each single column (or attribute) are stored contiguously, should be more efficient. This efficiency has been demonstrated in the warehouse marketplace by products like Sybase IQ [FREN95, SYBA04], Addamark [ADDA04], and KDB [KDB04]. In this paper, we discuss the design of a column store called C-Store that includes a number of novel features relative to existing systems.

With a column store architecture, a DBMS need only read the values of columns required for processing a given query, and can avoid bringing into memory irrelevant attributes. In warehouse environments where typical queries involve aggregates performed over large numbers of data items, a column store has a sizeable performance advantage. However, there are several other major distinctions that can be drawn between an architecture that is read-optimized and one that is write-optimized.

Current relational DBMSs were designed to pad attributes to byte or word boundaries and to store values in their native data format. It was thought that it was too expensive to shift data values onto byte or word boundaries in main memory for processing. However, CPUs are getting faster at a much greater rate than disk bandwidth is increasing. Hence, it makes sense to trade CPU cycles, which are abundant, for disk bandwidth, which is not. This tradeoff appears especially profitable in a read-mostly environment.

There are two ways a column store can use CPU cycles to save disk bandwidth. First, it can code data elements into a more compact form. For example, if one is storing an attribute that is a customer's state of residence, then US states can be coded into six bits, whereas the twocharacter abbreviation requires 16 bits and a variable length character string for the name of the state requires many more. Second, one should *densepack* values in storage. For example, in a column store it is straightforward to pack N values, each K bits long, into N * K bits. The coding and compressibility advantages of a

2. Data Cubes

Introducing Data Cubes

Operations: Slicing and Dicing

Slicing: select a single value in one of the dimensions to create a smaller cube with one less dimension

Operations: Slicing and Dicing

Dicing: select specific values of multiple dimensions to create a new subcube

Dice for (season = winter or spring) and (location = Venice or Florence) and (item = components or clothing)

Operations: Roll up and drill down Rollup: Moving from a finer to a coarser granularity

Operations: Roll up and drill down

Drill-down: Moving from a coarser to a finer granularity

Partitioning granularity in data cubes

Different partitioning may be useful for different applications

- Q: I want the aggregates per month. What if I set my partitioning based on Full Date and computed the data cube? Can I avoid recomputing the cube?
- Q: What about if I had set my partitioning based on Year?

How to pick the right partitioning granularity?

First, why does this matter?

• If this query is being run once on a petabyte sized warehouse, it is important to get it right!

Think about all the ways you want to slice and dice your data

Pick as fine a granularity of partitioning so that you can recreate all the aggregates, but not so fine as to blow up the query result

- The query result size grows exponentially in the attributes
- This is known as the curse of dimensionality

OLAP summary

OLAP is a specialization of relational databases to support analytical processing and report generation

- Typically done in large "batch" operations on the entire database
- Rule of thumb: pick as "coarse-grained" materialized views or query results as will allow you to construct all the cross-tabs that may be necessary

The concepts of OLAP data cubes, hierarchies, slicing/dicing, and rollup/drilldown are valuable to describe what you're doing when you are exploring your data

Data warehouses vs Data Lakes

Data cubes

- Slicing and dicing
- Rollup and drill-down
- Selecting partitioning granularity

3. A brief intro to HTAP Databases

Slides adapted from *SIGMOD'22 Tutorial HTAP Databases: A Tutorial* by Guoliang Li and Chao Zhang

Motivation

HTAP: Hybrid Transaction Analytical Processing

 Gartner's definition in 2018: supports weaving analytical and transaction processing techniques together as needed to accomplish the business task.

Motivation

- Rule of thumb 1: row store is ideal for OLTP workloads
 - Row-wise, update-heavy, short-lived transactions
- Rule of thumb 2: column store is best suited for OLAP workload
 - Column-wise, read-heavy, bandwidth-intensive queries

A trade-off for HTAP databases

- Workload isolation: the isolation level of handling the mixed workloads
- Data freshness: the portion of latest transaction data that is read by OLAP
- Trade-off for workload isolation and data freshness
 - High workload isolation leads to low data freshness
 - Low workload isolation results in high data freshness

An Overview of HTAP Architectures

- (a) Primary Row Store + In-Memory Column Store
- (b) Distributed Row Store + Column Store Replica
- (c) Disk Row Store + Distributed Column Store
- (d) Primary Column Store + Delta Row Store

(a) Primary Row Store+In-Memory Column Store

(b) Distributed Row Store+Column Store Replica

(c) Disk Row Store+Distributed Column Store

(d) Primary Column Store+Delta Row Store

Node 3

Column Store

A summary of HTAP databases

Category	HTAP Databases	OLTP Throughput	OLAP Throughput	OLTP Scalability	OLAP Scalability	Workload Isolation	Data Freshness
Primary Row Store+ In Memory Column Store	Oracle Dual-Format SQL Server, DB2 BLU	High	High	Medium	Low	Low	High
Distributed Row Store + Column Store Replica	TiDB, F1 Lightning SingleStore	Medium	Medium	High	High	High	Low
Disk Row Store + Distributed Column Store	MySQL Heatwave, Oracle RAC	Medium	Medium	Medium	High	High	Medium
Primary Column Store + Delta Row Store	SAP HANA (without scale-out), Hyper	Medium	High	Low	Medium	Low	High
